11. Rook

Program Name: Rook.java Input File: rook.dat

You're playing chess on a nice $n \times m$ board. Your opponent has decided to place k rooks around the board. How many positions do you have to safely place your pawn? A rook can move only horizontally or vertically and capture horizontally or vertically.

Input

The first line of input consists of a single integer, t, indicating the number of test cases that follow.

For each test case, there will be three space-separated integers, n, m, k on a single line, where n represents the number of rows, m represents the number of columns, and k represents the number of rook positions. The next k lines have two space-separated integers each, representing the row and column placement of a rook. All positions are 0-indexed.

Output

For each test case, print on its own line number of locations you can place your pawn on the board.

Constraints

```
1 \le t \le 15

1 \le n, m \le 1000

0 \le k \le n * m
```
